

**Prepared by:**

**Prepared For:** Dr. Samad Kolahi

**Dated:** Wednesday, 7 May 2014

**Subject:** ISCG 8046 (Cloud

Computing)

“Wherever this assignment draws on the work of others, such sources is clearly acknowledged”.

## **Abstract:**

Cloud Computing is the most recent term in today's world. Researcher's hard work gives birth to new terms like virtualization, utility computing, distributed computing, and networking. Cloud computing has many benefits like pay as per use, less cost of ownership, offering hardware and software as services, on request services and many more.

It also helps small and medium sized organizations to concentrate on their business rather than worrying about infrastructure. It means that these organizations have to expand their platforms and applications to meet business needs, but with the help of cloud they can simply buy these services from cloud service providers, and they can focus on their business.

The world's view about cloud will change in the future. Now a day's many organizations do not believe that how a single provider can protect their sensitive and confidential data, while they think that they can do this work better than a service provider. No doubt security is the main issue with cloud.

This report covers Cloud Computing as general which include topics like a new approach of Cloud computing, security related concerns, Security challenges in cloud computing, Performance analysis, Virtualization of cloud computing, Fault tolerance challenges, Cloud monitoring and so forth.

This report provides a brief introduction and history of cloud computing. After that it covers why the cloud usage is increasing these days and how it grows over a period of time. Then it covers the latest development which includes research paper summary, and the latest trends of cloud computing.

After this it covers the impact of cloud computing on social, education and business. It also includes the advantages, disadvantages, a future prospective and most important the researcher's efforts to provide a new platform to cloud computing.

In Conclusion, I would like to say that it is an emerging technology; researchers are doing very hard work to overcome the flaws present in this. They will soon achieve their targets.

## Introduction

“Cloud computing is a model for enabling convenient, on-demand network access to a shared pool of configurable computing resources (e.g., networks, servers, storage, applications, and services) that can be rapidly provisioned and released with minimal management effort or service provider interaction.” (Popescu, 2009)

Cloud Computing is prospective of information mechanization. It expresses all the major flows in the design and employment of computer architecture, and it closely connected to other parts such as big data and internet. It is a crucial movement in technology where applications do not depend on the specific part of hardware and software unless resources can be employed according to the needs of the user. (Half, 2013)

Cloud Computing is a union of technologies, which makes IT infrastructure and applications extra effective, more transposable and more accessible. It helps organizations to incline new services and distribute resources very quickly according to the needs of business. It provides self-service for users to access the computing resources while managing suitable levels of control. It provides ways to maintain hybrid computing surroundings, together on and off premise, depending on cost, capacity needs, and more factors. (Half, 2013)

In simple words, Cloud Computing can be defined as outsourcing their hardware or applications and running them on a different platform known as a cloud. (Chun, 2012)

In the present scenario most of the companies search and accommodate cloud computing services. There are many reasons for that; the main and major reason is cost. Small organizations cannot manage a large bulk of hardware nor the staff who maintains it. Large organizations can easily bear this cost, but why they waste their investments in large data centers when they can easily buy these services from the cloud computing providers according to their demand and usage. Moreover, they have to pay according to services utilize by them. It is just same as buy vs. rent picture. (Chun, 2012)

## History about Cloud Computing

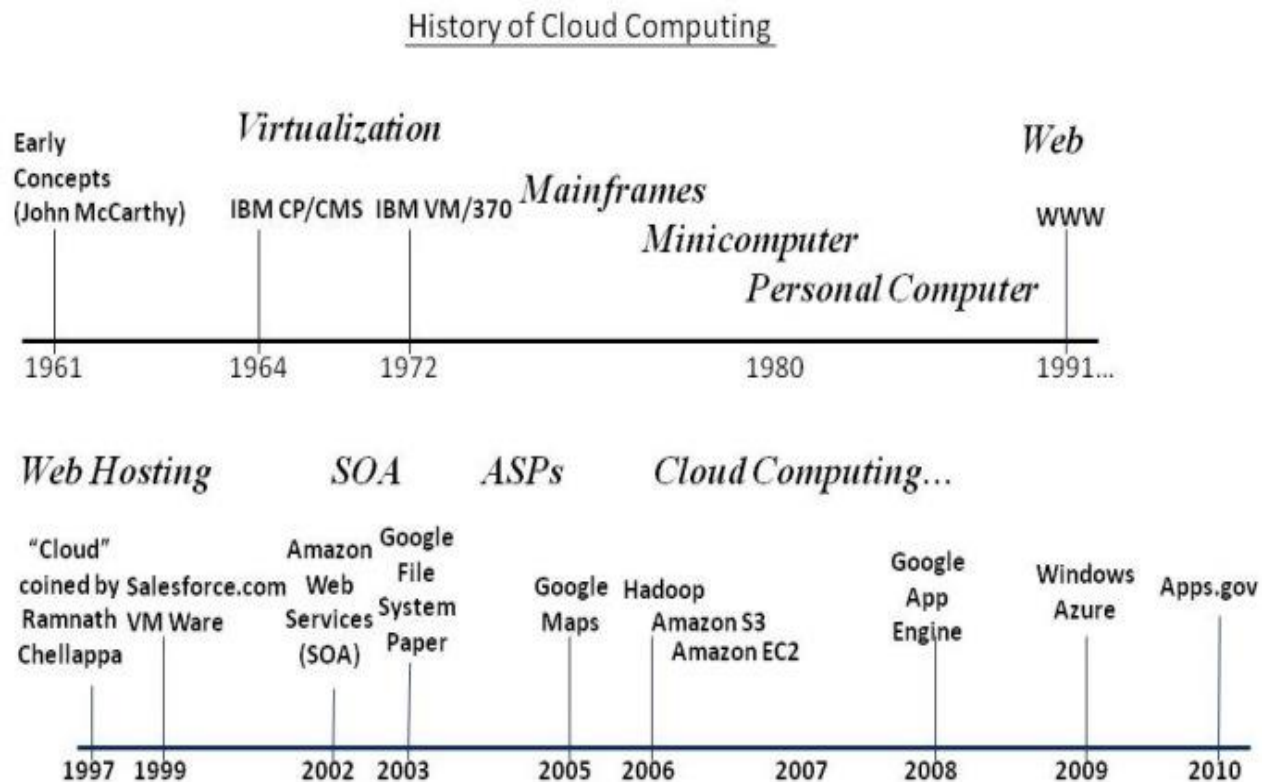

Figure 1: **The History of Cloud Computing** (Daconta, 2014)

As the figure 1 describes about the history of cloud computing. The image clearly depicts that in 1961 Professor John McCarthy suggested that computing can be formulated as public service. After that from 1964 to the 1972 IBM operating system uses the concept of virtualization. In 1991, the World Wide Web familiarizes the Internet. The term Cloud is used for the first time in 1997. Then in 1999 Salesforce.com and VMware came into existence. Amazon Web services and SOA emerges begin in 2002 and in the 2003 Google file system started. Google maps started in 2005 and Hadoop started, for Amazon S3 and EC2. In 2008 Google application launched and Microsoft Azure came into existence in 2009. After that in 2010 GSA's apps.gov and federal cloud first policy started. (Daconta, 2014)

## Reasons for cloud usage (Half, 2013)

Presently, Cloud is used for various reasons. It is clear from the image 2 that different people use cloud for different reasons. The various reasons are explained below. (Half, 2013)

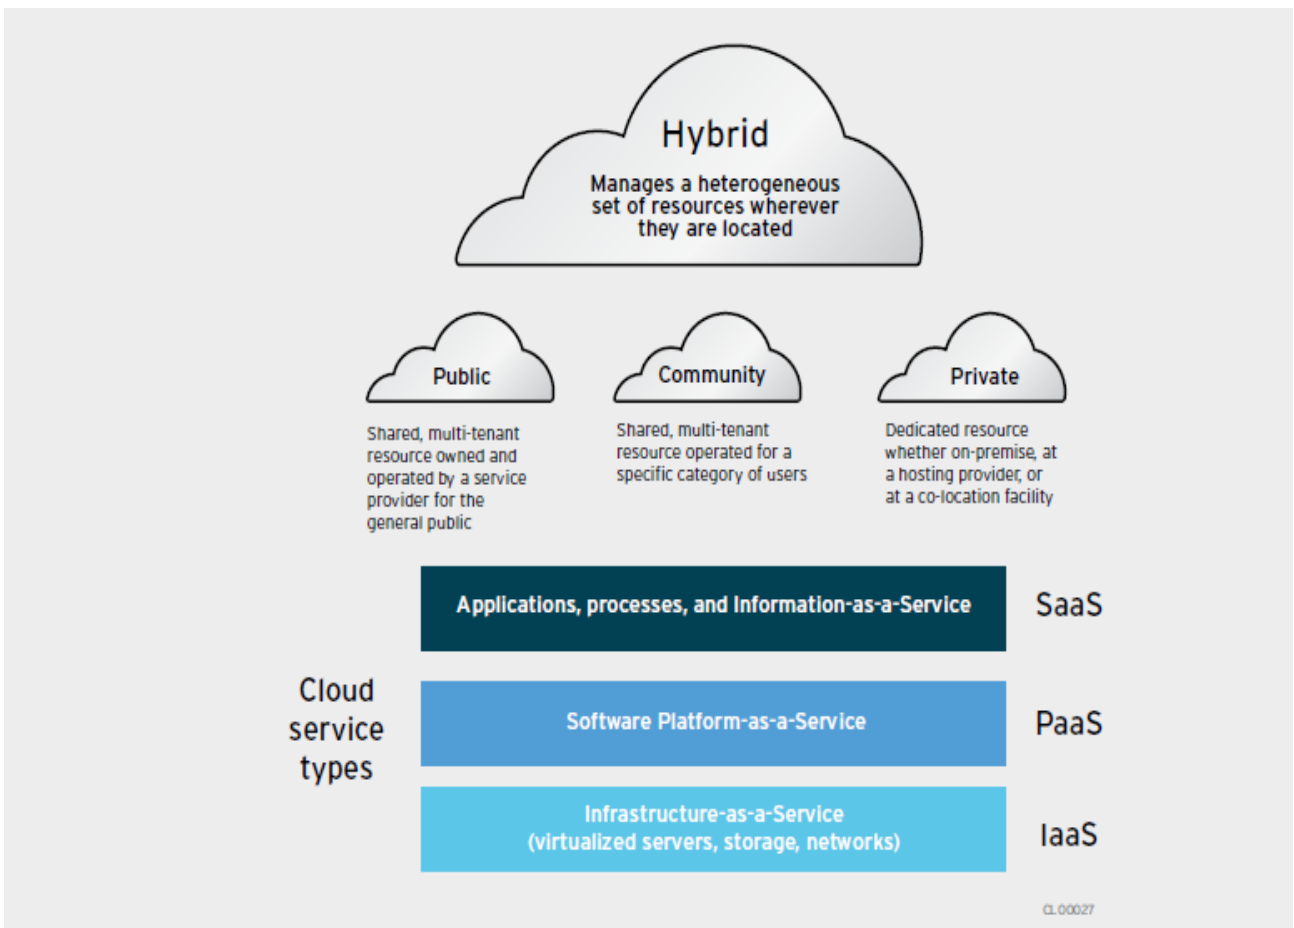

Figure 2: **Cloud Computing.** (Half, 2013)

### Resource abstraction and pooling:

Computer resources are shared by multiple users by accepting multi-tenant model where resources are allocated or reallocated to multiple consumers according to their needs and resources could be either physical or virtual. The users have limited control and knowledge

about the accurate location of the service provider. Examples of resources are like virtual machines, storage, memory, network bandwidth, and processing.

### **Network Central:**

Cloud computing is network centric irrespective of whether it is implemented within a one company or as a public cloud. Services are feasible over the network and approached by standard systems, mostly by using web protocols.

### **Simple, a fast arrangement of resources:**

Cloud computing helps to make the IT infrastructure more rapid by bringing new resources in the market and user can easily use these resources as he needed, without interacting with human even though this usage depends upon the policy between vendor and user.

### **Rapid and elastic scaling**

In Cloud atmosphere, resources can be used according to the demand and demand can be increased by user any time. On the other hand demand can be decreased anytime, when there is no need of that.

### **Utility pricing**

Utility pricing is also known as “Pay-Per Use”, which means what you use only that much you have to pay. Just like Electricity Meter where you get the bill only for the electricity you use and in a cloud you will pay according to the service which may include bandwidth, storage, active user accounts, or CPU usage.

## Analysis of Cloud Computing

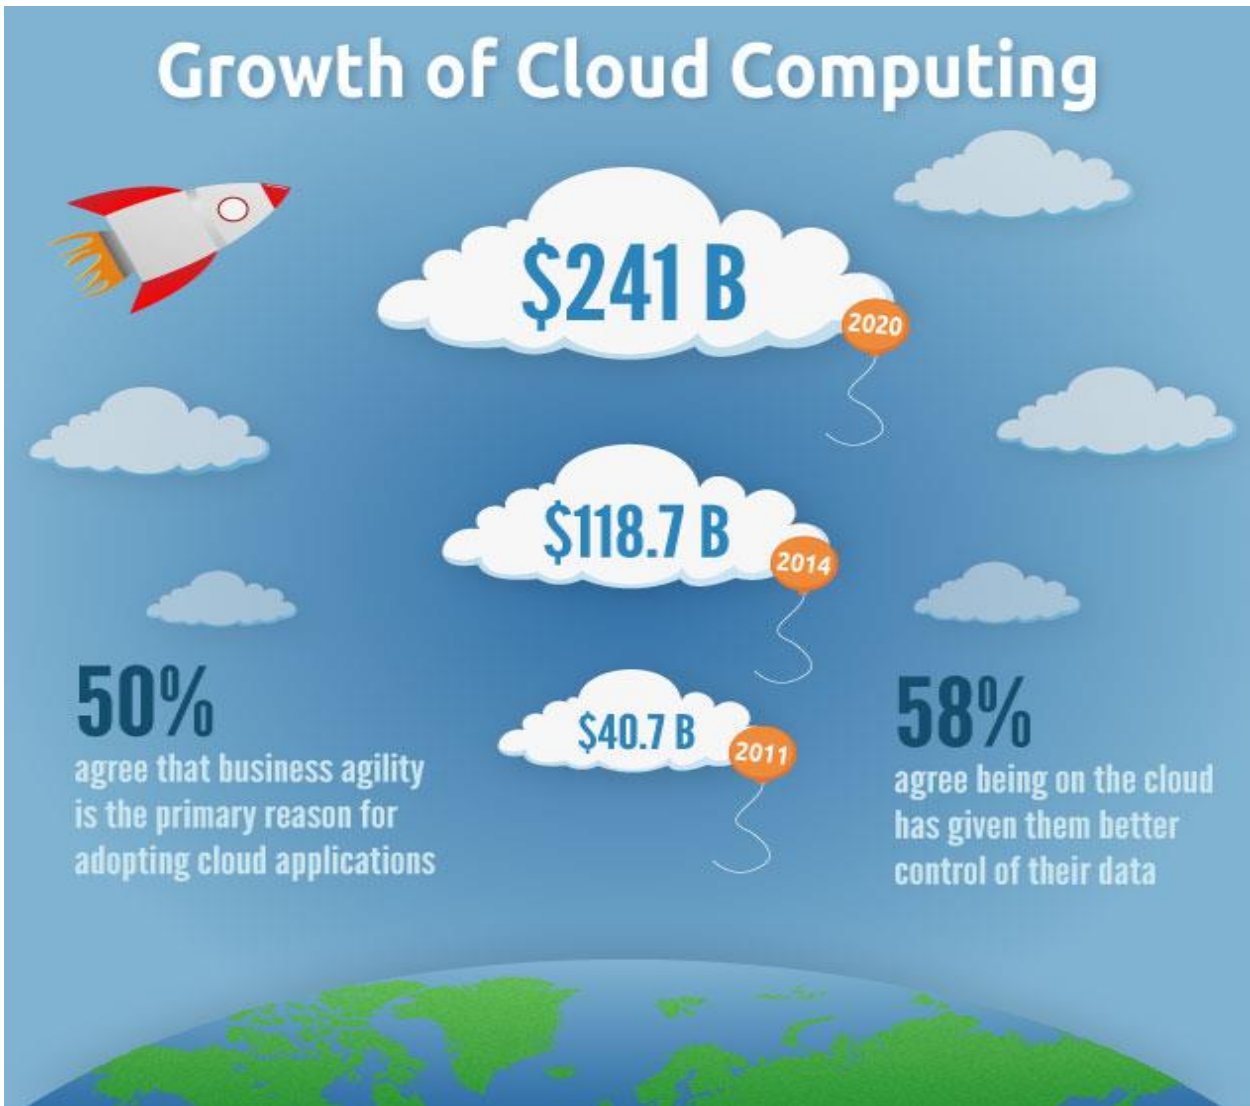

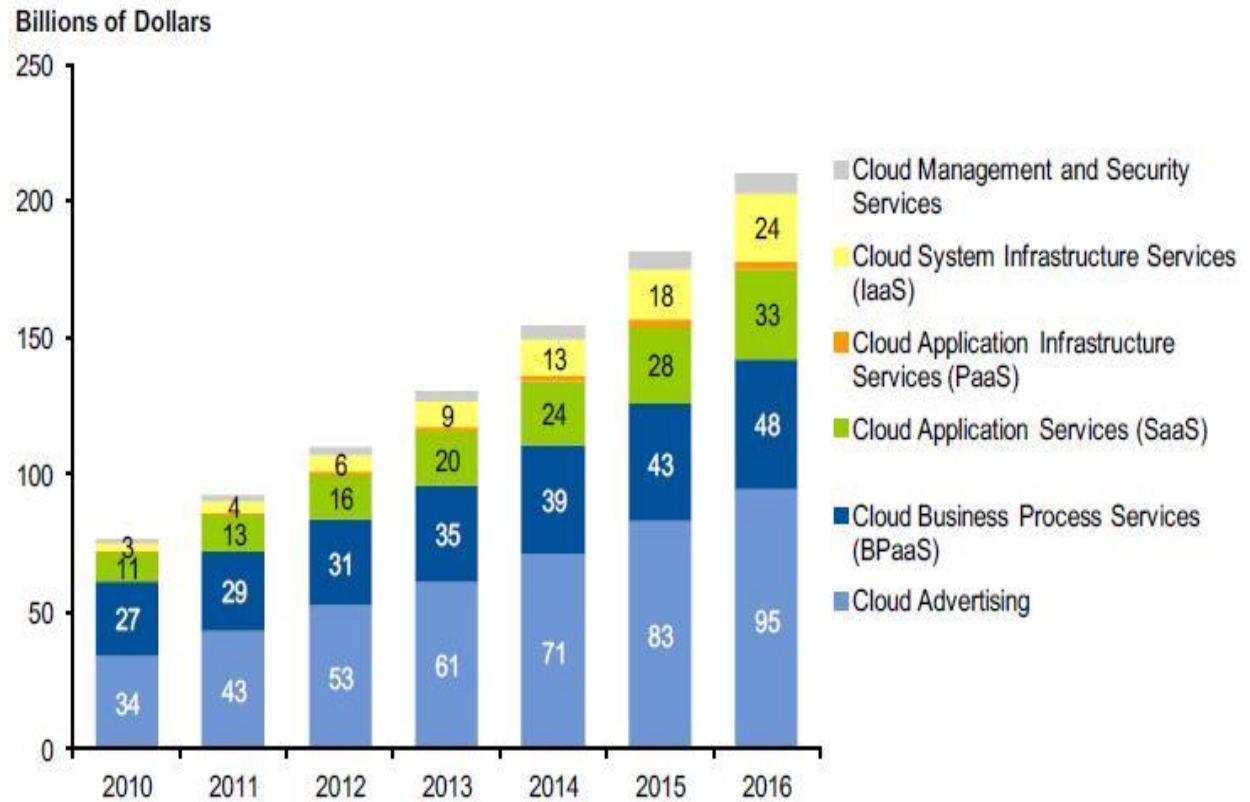

Figure 3: **The Growth of Cloud Computing from 2011 to 2020** (Lance, 2012)

In the above image growth of cloud computing from the time period from 2011 to 2020 has shown. It depicts that 50-percent people agree business rapidness is one main reason for adopting cloud applications while on the other hand, 58-percent people agree that they can better control their data when the data is on the cloud. Besides that it also shows the business income is increasing because of the cloud. (Lance, 2012)

### Public Cloud Services Market by Segment, 2010-2016

Source: Gartner (February 2013)

Figure 4: **Public Cloud Services Market by Segment** (Columbus, 2013)

Figure 4 predicts that popularity of Infrastructure as a Service will gain a year progress rate of 41.3 percent by 2016. This growth analysis between various services of cloud computing such as PaaS, SaaS, IaaS, BPaaS, and Cloud Management and Security Services and between the time period of 2010 to 2016. (Columbus, 2013)

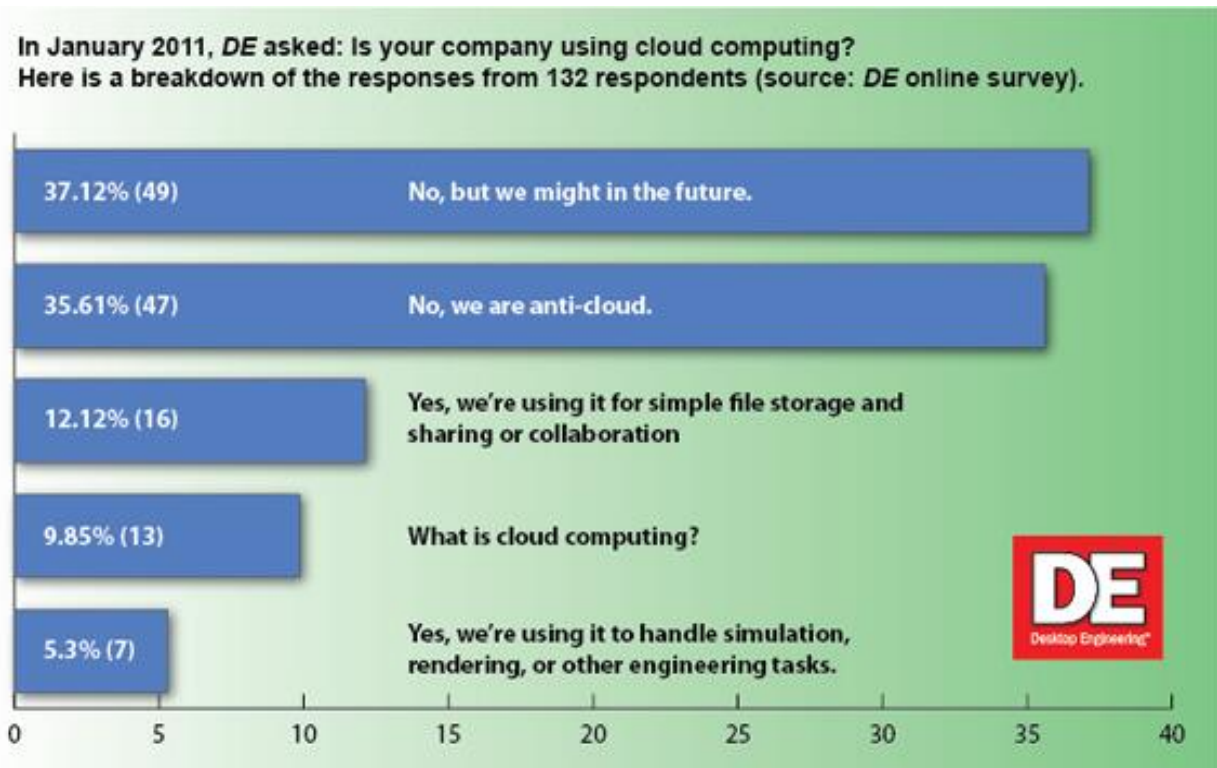

Figure 5: **Online Survey result by DE in 2011** (Kenneth, 2011)

Figure 5 shows the result of an online survey taken by DE Company which wanted to take people views about Cloud Computing. When they organized a survey and the results came, the results were shocking after as it showed that; 37.12-percent people do not use a cloud but they might use in the future, and 35.61-percent people are anti about a cloud because they do not feel that their data is secured on a cloud and more over the cost of moving the present infrastructure on the cloud is very high. Another reason people do not like the change, they are happy with what they are using. 12.12-percent people are using a cloud but for simple file storage and sharing or collaboration. This survey shows that 9.85-percent people do not have any idea of the cloud and only 5.37-percent handling it for simulation rendering and for an engineering task. (Kenneth, 2011)

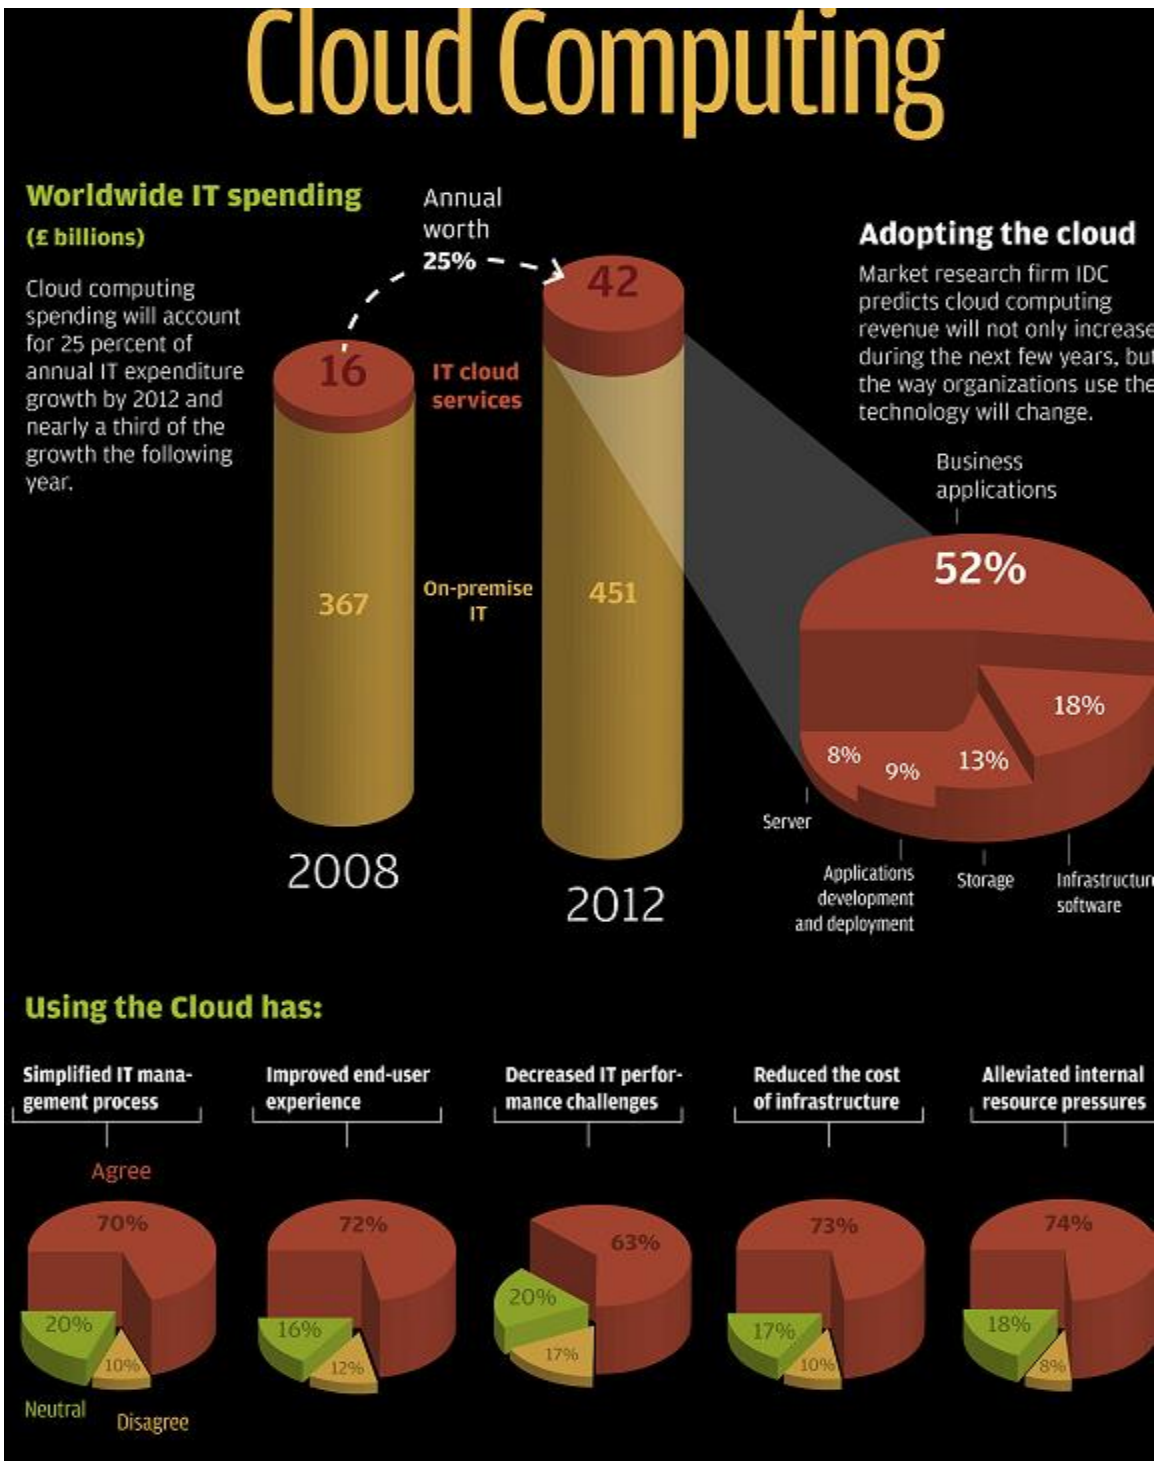

Figure 6: Annual I.T Expenditure Growth (Zenoss, 2011)

Figure 6 explains that at worldwide IT expenditure includes 25 percent on Cloud computing by 2012 and moreover, it also predicts that revenue will not only increase during the next few years, but the way companies use technology will also change. It also shows that how cloud could benefit people; 70 percent agrees that Cloud simplified IT management process, 72 percent agrees that it improved end user experience, 63 percent agrees that cloud declined IT performance challenges, 73 percent agrees that cloud reduced the expense of infrastructure, while 74 percent says that it alleviates the internal resource pressure. (Zenoss, 2011)

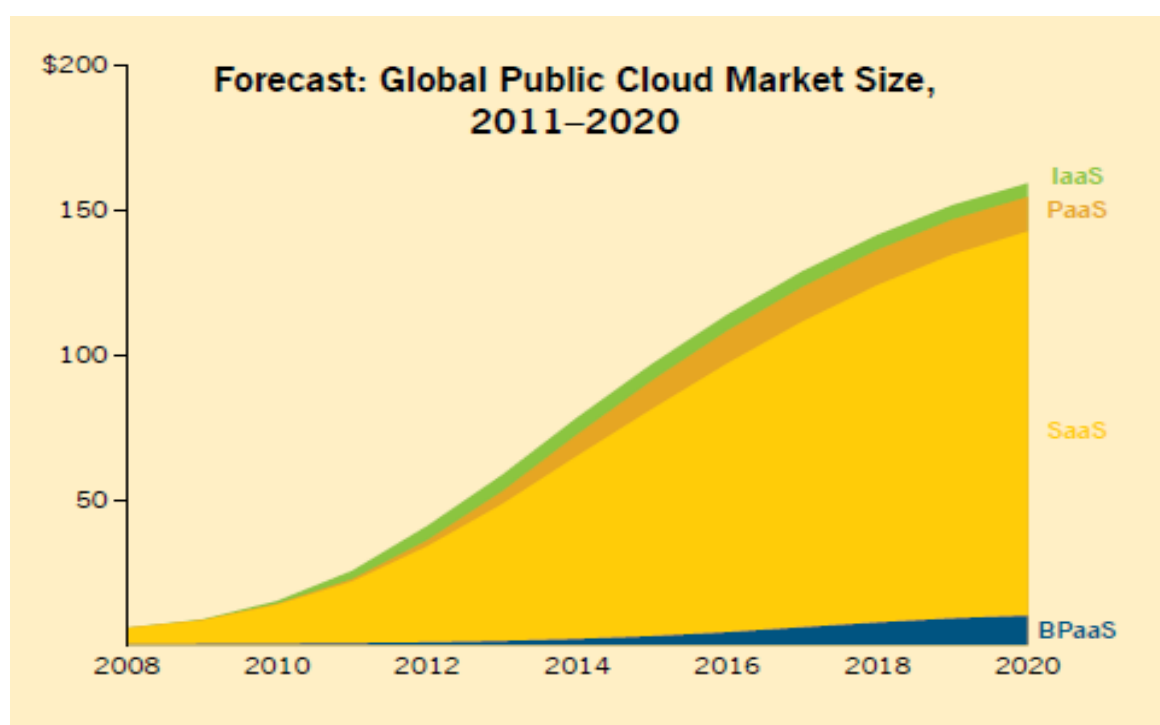

Figure 7: **Global Public Cloud Market Size 2011-2020** (Admin, 2012)

Figure 7 predicts that Cloud market size will dramatically increase from 2011 to 2020. It shows the comparison of different services, IaaS, PaaS, SaaS and BPaaS and out of each service SaaS is used majorly while IaaS is on the top. (Zenoss, 2011)

## Technical Details of Cloud Computing

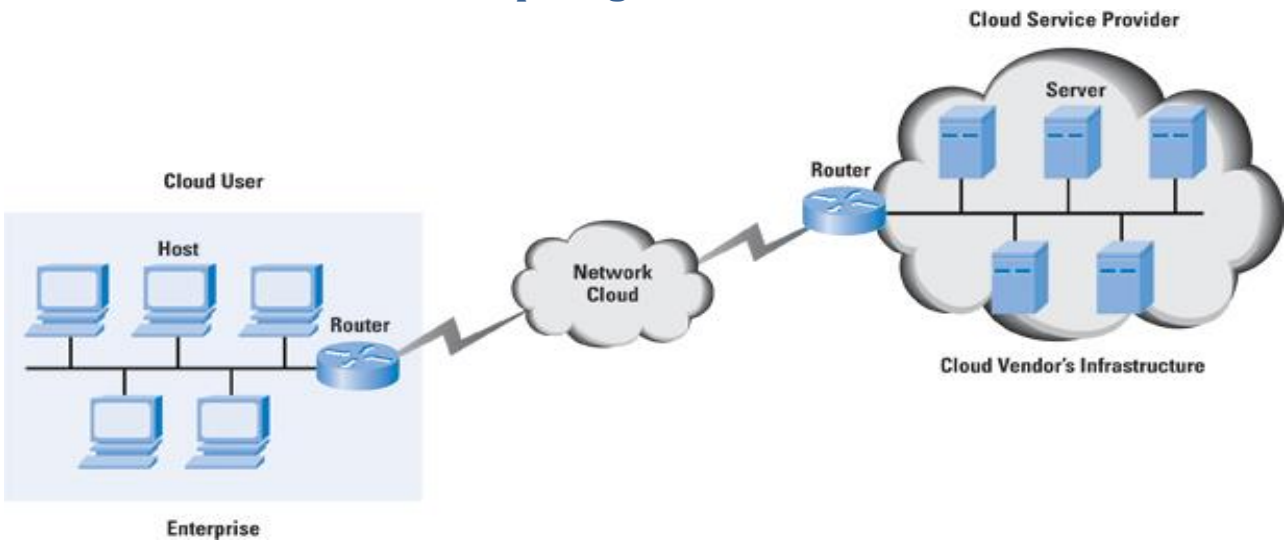

Figure 8: **Overview of Network Diagram of Cloud Computing** (Sridhar, 2009)

This describes how the communication between client and vendor happens. It also shows the Cloud Vendor's infrastructure and cloud user.

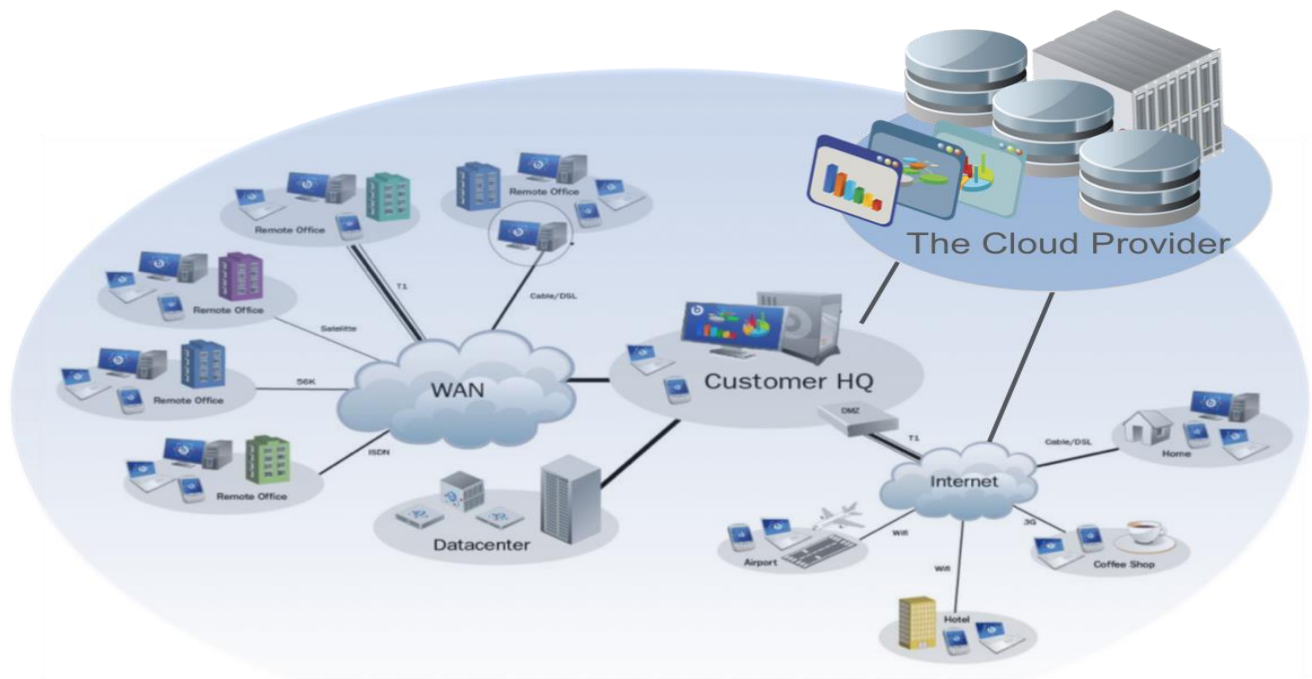

Figure 9: **Cloud computing Network** (IRDC3DMW, 2012)

Figure 9 shows the cloud computing network; in this cloud vendor is providing its services to different users at one time. There is customer head quarter and many users are connected with the help of wide area network. Customer HQ is connected to cloud vendor as well with the data centre.

Property	Different Platforms				
	Amazon Elastic Compute Cloud (EC2)	Google App Engine	Microsoft Azure	Sun Network.com (Sun Grid)	GRIDS Lab Aneka
Focus	Infrastructure	Platform	Platform	Infra-structure	Enterprise clouds
Service Type	Compute, Storage (Amazon S3)	Web Application	Web and non-web application	Compute	Compute
Virtua-lization	OS level running on a Xen hypervisor	Application container	OS level through fabric controller	Job management system (Sun Grid Engine)	Resource manager and scheduler
Dynamic negoti-ation of QoS	None	None	None	None	SLA-base resources reservation
Web APIs	Yes	Yes	Yes	Yes	Yes
User Access interface	Amazon EC2 command-line tools	Web-based administration	Microsoft windows azure portal	scripts, Sun Grid web portal	Work-bench, web-based portal
Value-added service providers	Yes	No	Yes	Yes	No
Progr- amming frame-work	Amazon Machine Images (AMI)	Python	Microsoft.NET	Solaris OS, Java, C, C++, FORTRAN	APIs supporting models in c# .Net

Table 1: **Comparison of some cloud computing platforms** (Nawsher Khan, 2011)

In the above table there is comparison of different cloud vendors on the various bases like what kind of services they are offering, about programming frame work, user access interface and so on.

## **Latest Development in Cloud Computing**\_(Allouche, 2013)

Cloud Computing is continuously chosen by organizations in various shapes, moreover, it is regularly conforming to the dynamic demands of businesses and providers. Companies are looking for an extended phrase plan to join a system of cloud, where providers constantly provide better advantages, like big data analytics.

Figure 10: **Transferring of data between different systems** (Allouche, 2013)

### **The rise of hybrid cloud:**

As we all know presently cloud computing is dominating these days, it is very hard for businesses to choose only one cloud services and fix to it. According to the Virtustream report, they found that most of the businesses now days are adopting multiple cloud services from different vendors to meet diverse demands which include a mixture of private and public IaaS cloud. This bulk of cloud spread out has led to worry whether trade can mark their assets and concentrating efficiently, and care for every cloud they are working. As long as it looks that organizations cannot stay on one choice, an increased acceptance of hybrid cloud will simplify their problem of different cloud service providers as they will get hybrid service from one vendor.

### **Big data analytics:**

Big data is challenging with distributed computing and always an issue for tech broadcast title, but various vendors and users are presently planning to merge these two. “Big data as a service” looks like the best practical option for data analytics, as it is expandable and within the range of any company, irrespective of its size and resources. Cloud providers are overwhelming the technical hurdle by converting Hadoop from an open origin platform to an enterprise – ready aid, this all they will do without the help of data scientist.

Figure 11: **Cloud Service to different devices** (Allouche, 2013)

### **SMB application protection:**

It has long been touted that distributed computing gives a colossal point of interest to little and medium-measured organizations, and cloud suppliers are as of now discovering better approaches to help bring down the playing field. While most little organizations can't bear the cost of a whole provision testing the system or costly appliances to check well being inside, cloud requisition security is making it conceivable to do simply that. This innovation permit's organizations to the output source code to their web requisitions for any progressions with a specific end goal to distinguish potential digital assaults and since it is on the cloud, it is accessible on interest.

### **Emphasis on performance**

While security and misfortune of control were the essential concerns of IT supervisors and when the cloud initially arrived, it looks like that the fundamental stress is currently on cloud execution. Organizations need to realize that the administration will be dependable and perform up to the limit they require without collapsing throughout basic periods. In the meantime, since the cloud is currently an attempted and tried innovation, associations progressively believe it with delicate requisitions.

### **Gamifications**

Gamification has been on the ascent around showcasing experts for a few years. In 2012, Gartner anticipated that by 2014, 70 for every penny of Fortune 2000 organizations might have no less than one cloud-based provision that uses amusement hypothesis, along these lines far gamification has kept on gaining in reputation. With such a variety of profits, from expanded purchaser interest to expanded access to conduct dissection, organizations are paying thought to what diversions can accomplish for their brand.

### **Emerging Insurance Practices in Cloud Computing (Tumpowsky, 2014)**

The Insurance industry is ceaselessly searching for the easiest, the most productive strategy for giving purchasers the best administration, while in the meantime attempting to decrease general working costs. While protection suppliers investigate the right choices for their organizations, one thing is sure: Cloud-based situations are generally safe results that empower provisions to build business esteem. Research has demonstrated that running desktop requisitions in the cloud might be engaging on the grounds that it decreases quality and increases security.

### **“Use of Cloud computing for managing Health Information” (IT Health Board, 2014)**

In New Zealand, Health board is opting cloud for managing health information of patients on cloud. Cloud computing is good and attractive choice for health providers and funders because of its cost and availability.

Although it has many issues like security but it is matter of trust but the risk is high if the vendor is situated overseas. According to the “Health Information Privacy Code 1994”, it is the duty of health organizations to keep the data secure of patients, doctors and so on.

To avoid the overseas risk, New Zealand government has taken two steps for avoiding this issue of security.

- **“New Zealand domiciled cloud computing”:** Health agencies have to take prior confirmation from this agency that they are not going to store any health data in cloud if it is overseas.
- **“New Zealand Government Cloud Program”:** This is the program run by the government to recognize how the cloud technology is used by the government department in New Zealand.

### **IBM invests \$8 million in Spanish cloud data center: (Cheney, 2013)**

IBM wants to gain the market in cloud computing and as we know Google and Amazon are the leading competitors, so to stop it IBM started its twenty sixth cloud centre in Spain. Its total cost to start new cloud center is \$8 million.

## **Researchers Works on Cloud Computing** (Wikipedia, 2014)

- The “Academic Cloud Computing Initiative (ACCI)” was reported as a multi-college undertaking in October 2007 and intended to improve scholars specialized learning to address the tests of distributed computing.
- “UC Santa Barbara” discharged the early open source in April 2009 like Platform-as-a-service, AppScale, which is equipped for working Google App Engine requisitions at a scale on a large number of bases.
- The “St Andrews Cloud Computing” Co-research center was started in April 2009, keeping tabs on exploration in the vital new zone of distributed computing. One of a kind in the UK, StACC plans to turn into a universal middle of supremacy for exploration and educating in distributed computing and gives counsel and data to organizations curious in cloud-based services.
- The “TClouds (Trustworthy Clouds)” venture was begun in October 2010, financed by the European Commission's seventh structure Program. The task's objective is to study and review the legitimate establishment and structural configuration to assemble a strong and reliable billow of-cloud foundation on top of that. The task likewise creates a model to show its effects.
- The “Trust Cloud” examination venture was begun in December 2010 by HP Labs Singapore to address translucent and responsibility of distributed computing through criminologist; information driven approaches embodied in a five-tier Trust Cloud structure. The group recognized the demand for screening information wheel of life and moves in the cloud, prompting the handling of basic distributed computing security concerns, for example, cloud information spillages, cloud responsibility and cross-national information moves in transnational clouds.
- The IRMOS EU-supported venture created a continuous cloud stage in January 2011, empowering intuitive provisions to be performed in cloud infrastructures.

- Two Indian Universities i.e. College of Petroleum and Energy Studies and The University of Technology and Management presented distributed computing as an area of study in India in June 2011, as a team with IBM.
- “The High Performance Computing Cloud (HPCCloud)” task commenced pointing at figuring out the potential outcomes of improving execution on cloud situations in July 2011 while running the logical requisitions – improvement of HPCCloud Performance Analysis Toolkit which was subsidized by CIM-Returning Experts Program – under the coordination of Prof. Dr. Shajulin Benedict.
- The “Telecommunications Industry Association” created Cloud Computing White Paper in June 2011, to dissect the combination tests and chances between cloud administrations and accepted U.S. telecommunications standards.
- The VISION Cloud EU-subsidized task proposed a building design alongside a usage of a cloud environment for information escalated administrations intending to give a virtualized Cloud depository infrastructure.
- The Center for Development of Advanced Computing discharged an open source, complete cloud administration, a programming suite called "Meghdoot" in October 2012.
- The Bonfire project propelled different-site cloud examination and testing office. The office gives translucent admission to cloud assets, with the control and recognizability important to architect future cloud innovations, in a manner that is not confined, for instance, by present plans of business miniature.

## Summary of Papers

### **Paper 1: “A New Approach of CLOUD: Computing Infrastructure on Demand” (Kamal Srivastva, 2011)**

This paper describes that Distributed computing portrays how PC projects are facilitated and worked above the Internet. The essential characteristic of distributed computing is that product and the data both, held in it live on halfway found servers instead of on an end-client's workstation.

There are many organizations that suggest cloud computing administrations like Amazon suggest something many refer to as Google with its distributed computing offering, Amazon Elastic Compute Cloud (Ec2), Microsoft offers Microsoft Azure, and Google App Engine.

Cloud computing architecture built of two parts (hardware and application). These two segments have to perform jointly, seamlessly; otherwise distributed computing will not be feasible. Distributed Computing needs tricky communication with the hardware which is very important to make sure uptime of provision. If application break down, the hardware will not have the ability to force the information and implement confirm processes.

The Cloud Architectures location key challenges encompassing huge scale information transforming. In universal information handling it is challenging to get the same number of machines as a provision demands. Another, it is challenging to access the machines when one needs them. Next, it is troublesome to appropriate and coordinate a vast scale work on diverse machines, run forms on them, and procurement an alternate machine to acquire if one device falls flat. After that, it is challenging to auto scale all over dependent upon dynamic workloads. Last, but not least, it is troublesome to dispose of every one of those machines the point when the occupation is carried out. Cloud Infrastructure can tackle such challenges.

Cloud registering guarantees huge profits, however today there is security, protection, and different restraints that block an extensive venture selection of an outer cloud. Furthermore, expense profits for big organizations have not yet been obviously showed. The utilization of assets in Cloud configuration is as required, some of the time temporary or regular, along these lines, giving the most noteworthy use and an ideal result for the hard earned money.

## **Paper 2: "A Survey on data security issues in cloud computing: from single to multi clouds" (Mohammed A. AlZain, 2013)**

This paper tells that Distributed computing utilization has expanded quickly in numerous organizations. Distributed computing offers numerous profits regarding minimal effort and accessibility of information. The utilization of distributed computing has enhanced quickly in numerous associations. Little and medium organizations utilized distributed computing administrations for different reasons, including giving a quick gain approach to their requisitions and decreasing their foundation expenses. Distributed computing activities using in the USA will be at a 40% yearly development rate (CAGR) in the period of 2010 to 2015, and will cross \$7 billion by 2015. Likewise, analysts evaluated that 12 percent of programming business will move to distributed computing inside the following five years and the sum development of distributed computing business will arrive at \$95 billion.

Managing "single cloud" suppliers is getting less famous between clients because of potential issues, for example, administration accessibility disappointment and the likelihood that there are mischievous attackers in the distinct cloud. As of late, there has been progress en route "multi-mists", "intercloud" and "billow of-mists".

Any defect in software and hardware are called Byzantine error, which includes arbitrary faults, behavior faults, crash faults, and intrusion tolerance. The Byzantine fault tolerance is not good for a single cloud and if this kind of fault occurs in a specific system in the cloud, it is better to use a distinct operating system, and distinct hardware to make sure this defeat will not be transmitted to other areas of the similar cloud.

The DepSky system is used in areas of multi clouds which include 4 clouds and every cloud has its own compound. DepSky algorithm presents in users' system as a software library to exchange information with every cloud. The above mentioned four clouds act as a repository clouds, and DepSky library allows review and writing tasks with repository clouds.

In order to eliminate risk, users can adopt cryptographic ways to safe information stocked in distributed computing. If the data is small then hash function is good and if data is big in number then hash tree is a good way to protect the data. As we know cloud computing is at a rapid pace but security is always an issue for its environment.

### **Paper 3: “Beyond lightning: A Survey on security challenges in a cloud computing” (Chunming Rong, 2013)**

In this paper Google’s Kevin Marks said that the term cloud generates from the previous time, the Internet where it is drag like as a cloud. In the older system, the client information and computing forces are found in the client’s computer system; on the other hand, cloud computing resources are supplied in a large, abstracted (virtualized) infrastructure handled by skilled workers. The cloud ideal reduces installation, preservation, and operation of information structure, and lessens expenses while expanding system authenticity and productivity. A cloud system is also a customer favorable, in this way user needs less knowledge to operate.

The profits presented by distributed computing are legion. As stated by IDC the most advantageous parts of utilizing cloud incorporate, quick, and simple, sending, the pay-for every utilization model, and decrease of in-house IT finances. Notwithstanding, they additionally bring up that security is the most imperative issue to be tended to with a specific end goal to advertise the far reaching utilization of distributed computing. Security is always an issue for cloud computing.

Despite the fact that security concerns in old conversation frameworks likewise implement to the cloud, the utilization of distributed computing presents new strike aims that will create assaults either feasible or essentially less demanding to complete. The validation and authorization provisions for big business situations may wish to be changed to task with a cloud atmosphere. Crime scene investigation task may get to be substantially more challenging since specialists will be unable to get to framework fittings physically.

The accessibility of cloud administration suppliers is likewise an enormous concern, since if the cloud administration is disturbed; it influences a bigger number of clients than in the older model. Case in point, the late disturbance of the Amazon cloud administration brought down various sites including Reddit, Foursquare, and Quora. To wrap things up, virtual appliance security is likewise an issue. The hypervisor and virtual appliances utilized as part of cloud suppliers might additionally have vulnerabilities, as demonstrate by Xen. Such vulnerabilities speak to a much more genuine an issue in multi-occupant situations, where the trade off of virtual machines can influence all clients on the identical physical server.

In various regards, distributed computing speaks to outsourcing of calculation and stockpiling. Such contract out has been represented by “Service Level Agreements” (SLA) that detail least layers of execution that the client can want, e.g., 99.999% framework accessibility for every year. Customarily, be that as it may, SLA’s have not secured security viewpoints, for example, secrecy and trustworthiness.

Distributed computing movements the majority of IT foundation and information stockpiling to outsider suppliers, with two imperative outcomes: (a) Data holders have just restricted control over the IT framework, consequently information managers must create a system to command the implementation of their security strategies to guarantee information privacy and trustworthiness; (b) Cloud administration suppliers have over the top benefits, permitting them far reaching control and capability to change clients' IT frameworks and information. This point to a little faith matched when storing and offering information on a cloud, particularly in a plan of action which needs rigid safe information preparing keeping in mind the end goal to shield business engages.

Subsequently, a protected framework is vital to empower trusted information offering through untrusted cloud suppliers. The framework ought to besides force access control approaches of information managers, keeping the distributed storage suppliers or other un-approved clients from unlawfully getting to information.

While bulletproof secrecy safeguarding answers for the cloud keep an attractive objective; it is fair that as great as "large information" requires to be handled in the cloud, there are as of now no adequately productive instruments that can do this apart from allowing the cloud suppliers have entry to clear text information. In this way, there is a need for different instruments that can alleviate the reasons for alarm of clients that generally could be frightened off from utilizing the cloud.

Distributed computing is an exceptionally guaranteeing innovation that helps organizations decrease working expenses while expanding productivity. Despite the fact that distributed computing has been sent and utilized within preparation situations, security in distributed computing is still in its outset and requires more study consideration.

#### **Pape4: “Ostrato’s cloud Chosen to Power Fusion PPT Cloud Computing Interoperability and Portability Test Lab” (Close-up, 2013)**

In this paper Ostrato, a supplier of versatile cloud administration results, affirmed that its cloud administration chief, cloud, has been chosen “to power Fusion PPT's Cloud Computing Interoperability and Portability Test Lab”.

As stated by a discharge, by influencing cloud, an incorporated stage to help unite, scale and receive cloud administrations while conveying prevalent client knowledge, Fusion PPT, a distributed computing method and engineering firm, will propose its customers, an answer for a deal with their systems of cloud situations as a component of its Innovation lab.

Combination said it’s PPT's Innovation lab gives a proving ground that permits its clients to explore different avenues regarding a mixed bag of distributed computing transportability and interoperability instruments and results in various cloud situations. Utilizing this testing environment, Fusion can evaluate a provision's capacity to run on combined cloud frameworks, figure out if the requisition could be moved effectively between situations and assess how well the requisition connects with different administration suppliers and different instruments. As the spine of this framework, Ostrato's cloud will help Fusion PPT's clients with the capacity to procurement, represent and oversee different cloud benefits inside the Cloud Computing Interoperability and Portability Test nature.

Ostrato's interface is around the most easy to use, which not just drives esteem for Fusion PPT as an organization, additionally for our customers who profit from the improved client knowledge and capable instrument for a viable and safe cloud administration.

“The cloud business sector is rapidly growing. In view of the bearing that systems administration and processing have taken, more endeavors will need to ponder how to get a cloud stage conveyed and how to deal with their speculations once sent," said Jay Chapel, CEO of Ostrato. In this connection our cloud stage resolved Fusion PPT's Innovation lab, which gives endeavors intend to survey and assess the exceptional characteristics of a cloud system setup.

## **Paper 5: “A tenant-based resource allocation model for scaling Software –as-a-Service applications over cloud computing infrastructures” (Javier Espadas, 2013)**

Distributed computing gives on-interest admission to computational assets which jointly with pay-scrutinize plans of action, empower requisition suppliers consistently scaling their administrations. Distributed computing foundations permit making a fluctuating number of virtual device occurrences relying upon the provision requests.

A magnetic capacity for Software-as-a-Service (Saas) suppliers is having the promising to range boost or descend provision assets to just ruin and fee for the assets that are truly needed eventually in time; if finished effectively, it will be less costly than running on customary fittings by accepted facilitating.

Notwithstanding, actually when huge scale provisions are conveyed over pay per- utilization cloud high-execution foundations, practical versatility is not attained in light of the facts that sit methods and assets (CPU, memory) are idle, however owed to provision suppliers. Over and under equipment of cloud assets are still difficult issues.

This effort seeks to make a proper estimation for under and atop equipment of virtualized assets in cloud frameworks, particularly for SaaS stage organizations and introduces an asset assignment miniature to send Saas provisions over distributed computing stages by considering their multi-tenancy, accordingly making a practical nature.

In this substance, an occupant based miniature is displayed to handle over and under usage when SaaS stages are conveyed over distributed computing foundations. This ideal holds three reciprocal methodologies: (1) An occupant based segregation which exemplifies the execution of every occupant, (2) An occupant based burden adjusting which disseminates appeals concurring to the occupant data, and (3) an inhabitant based VM case distribution which decides the amount of VM examples required for a specific workload, taking into an account VM limit and occupant setting weight. In the wake of running all tests and reproductions, the effects were assembled and midpoints were computed. As a rule, over and Under-utilization midpoints were lessened yet midpoints for underutilization were factually revised.

## **Paper 6: “Performance analysis of HPC applications in the cloud” (Roberto R. Exposito, 2013)**

This paper tells that adaptability of High Performance Computing (HPC) provisions rely upon intensely on the proficient backing of system correspondences in virtualized situations. On the other hand, Infrastructure as a Service (IaaS) suppliers are also kept tabs on conveying frameworks with greater computation force attached by means of large velocity arranges as opposed to enhancing the adaptability of the correspondence middleware.

Virtualization is a system to sum up the fittings and framework assets from a likely working system, and it is a standout amongst the most critical advances that built the distributed computing standard conceivable. Infrastructure as-a-Service (IaaS) is a kind of cloud administration which effectively empowers clients to build a virtual group giving financially savvy results. Numerous exploration endeavors have been carried out in the most recent years to decrease the expense forced by virtualized situations, and because of this, distributed computing is turning into a magnetic alternative for High Performance Computing (HPC).

This paper breaks down the fundamental execution obstacles in HPC provision versatility on the Amazon Ec2 Cluster Compute stage: (1) assessing the correspondence execution on imparted retention and a virtualized 10 Gigabit Ethernet arrange; (2) evaluating the adaptability of delegate HPC codes, NAS Parallel standards, utilizing an essential number of centers, up to 512; (3) dissecting new bunch occasions (Cc2), the two regarding single occurrence execution, adaptability and expense productivity of its utilization; (4) proposing procedures for decreasing the effect of the virtualization expense in the adaptability of correspondence concentrated HPC codes, for example, the immediate entry of the Virtual device to the system and diminishing the amount of techniques for every case; and (5) introducing the synthesis of message-conveying with multithreading as the greatest adaptable and financially savvy choice for working HPC provisions on the Amazon Ec2 group Compute stage.

## **Paper7: “Secure virtualization for cloud computing” (Flavio Lombardi, 2011)**

Distributed computing selection and dispersion are undermined by uncertain security concerns that influence two together; the cloud supplier and the cloud client. ACPS might be sent on a few cloud results and can successfully screen the uprightness of visitor and framework parts while keeping completely translucent to virtual devices and to cloud clients. ACPS can mainly respond to security breaks and in addition advise a further security administration layer of such occasions.

The model is tried against viability and execution. Specifically: (a) viability is demonstrated trying our model against ambushes known in the written works; (b) an execution assessment of the ACPS model is completed under diverse sorts of workload. Effects show that our idea is versatile opposite to ambushes, and that the presented overhead is little when contrasted with given characteristics.

There are many cloud security issues. The main issue is a deficit of control and the first instance of that is where the administration client does not notice where precisely its information is put away and handled in the cloud. Computation and information are versatile and might be moved to frameworks the SU can't straightforwardly dominate. Above the Internet, information is allowed to address universal fringes and this can open to additional security dangers. A second illustration of misfortune of command is that the cloud supplier (CP) gets rewarded for working an administration he doesn't have a clue the points of interest have.

In this paper, authors have given a few contributions to secure clouds by means of virtualization. To begin with, they have recommended new progressed structural engineering (ACPS) for cloud assurance that can screen both visitor and middleware uprightness and ensure them from most sorts of attacks while keeping completely translucent to the administration client and to the administration supplier. Second, the projected structural engineering has been actualized altogether on present open source results, and both assurance adequacy and execution outcomes have been gathered and analyzed.

## **Paper 8: “Fault Tolerance-Challenges, Techniques and implementation in cloud computing” (Anju Bala, 2012)**

This paper examines the current deficiency tolerance systems in a cloud figuring dependent upon their strategies, equipment utilized and research confronts. Cloud virtualized framework structural engineering has been projected. In the planned framework autonomic shortcoming resistance has been executed. The trial effects show that the projected framework can manage different programming deficiencies for server provisions in a cloud virtualized nature.

Fault resistance is a significant interest to surety accessibility what's more dependability of basic administrations and requisition execution. To minimize disappointment effect on the framework and requisition execution, disappointments ought to be expected and proactively took care of. Flaw tolerance methods are utilized to anticipate these disappointments and take a proper activity before disappointments really happen.

In this paper two types of fault tolerance policies are discussed. One is Reactive and second is Proactive Fault resistance. Reactive fault resistance diminishes the impact of inefficacy on provision ability when the failure successfully happens. This policy includes few techniques like restart, job migration, and replication, retry, SGuard, and task resubmission. The second type of policy Proactive Fault Tolerance means to stay away from issues, slips and disappointments by foreseeing them and proactively trade suspected segments. A percentage of the procedures which are taking into account these strategies are Preemptive relocation, Software Rejuvenation and so forth.

Cloud virtualized framework structural engineering is likewise proposed dependent upon HAProxy. Autonomic fault tolerance is actualized managing different programming deficiencies for server requisitions in a cloud nature. The point is that when one of the server moves below par startlingly, association will naturally be diverted to the next server. Information mirror strategy is actualized on virtual nature. The exploratory outcomes are got, that accept the framework fault resistance.

## Paper 9:” Cloud monitoring: A survey” (Giuseppe Aceto, 2013)

This paper tells that Cloud Computing is broadly employed to convey benefits above the Internet for two specialized and conservative logics. The amount of Cloud-based administrations has expanded quickly and determinedly in the most recent years, along these lines is expanded the difficulty of the frameworks following these administrations. To appropriately work and oversee such difficulty foundations viable and persuasive the following is continually required.

Considering of Cloud is an assignment of central significance for two Providers and Customers. On one side, it is an essential device for supervising and overseeing equipment and programming foundations; on the additional, it gives data and Key Performance Indicators (KPIs) for two stages and operations. The constant screening of the Cloud and of its SLAs (for instance, regarding accessibility, delay, and so forth.) supplies the two Providers and the Consumers with data, for example, the assigned work created by the last and the execution and QoS proposed over the Cloud, additionally permitting to execute components to anticipate or recoup breach (for two Provider and Users). Observing is unmistakably applicable for all the exercises secured by the part of Cloud Auditor. In additional common terms, Cloud Computing includes numerous exercises for which noticing is the most important job.

### Cloud monitoring platforms and services.

Commercial platforms	Open source platforms	Services
CloudWatch [95]	Nagios [104]	CloudSleuth [112]
AzureWatch [137]	OpenNebula [105]	CloudHarmony [113]
CloudKick [96]	CloudStack ZenPack [108]	Cloudstone [114]
CloudStatus [48]	Nimbus [110]	Cloud CMP [116]
Nimsoft [97]	PCMONS [111]	CloudClimate [118]
Monitis [99]	DARGOS [128]	Cloudyn [119]
LogicMonitor [100]	Hyperic-HQ [138]	Up.time [120]
Aneka [101]	Sensu [139]	Cloudfloor [121]
GroundWork [129]		CloudCruiser [122]
		Boundary [136]
		New Relic [140]

Figure 12: Cloud monitoring platforms and services (Giuseppe Aceto, 2013)

Figure 12 shows the various cloud monitoring platforms and services available these days. It also shows the most spread business what a more open point of supply stages is for Cloud examining too as services that can aid clients to evaluate the execution and the believability of Cloud administrations.

Monitoring activities could be profoundly demanding regarding, figuring and communication assets, and accordingly as far as vitality and expense. An alternate significant test for cutting edge Cloud screening frameworks is that of executing noticing activities fulfilling their essential necessities (Completeness, Reliability, Accuracy and so forth.), yet minimizing the related vitality utilization and expense.

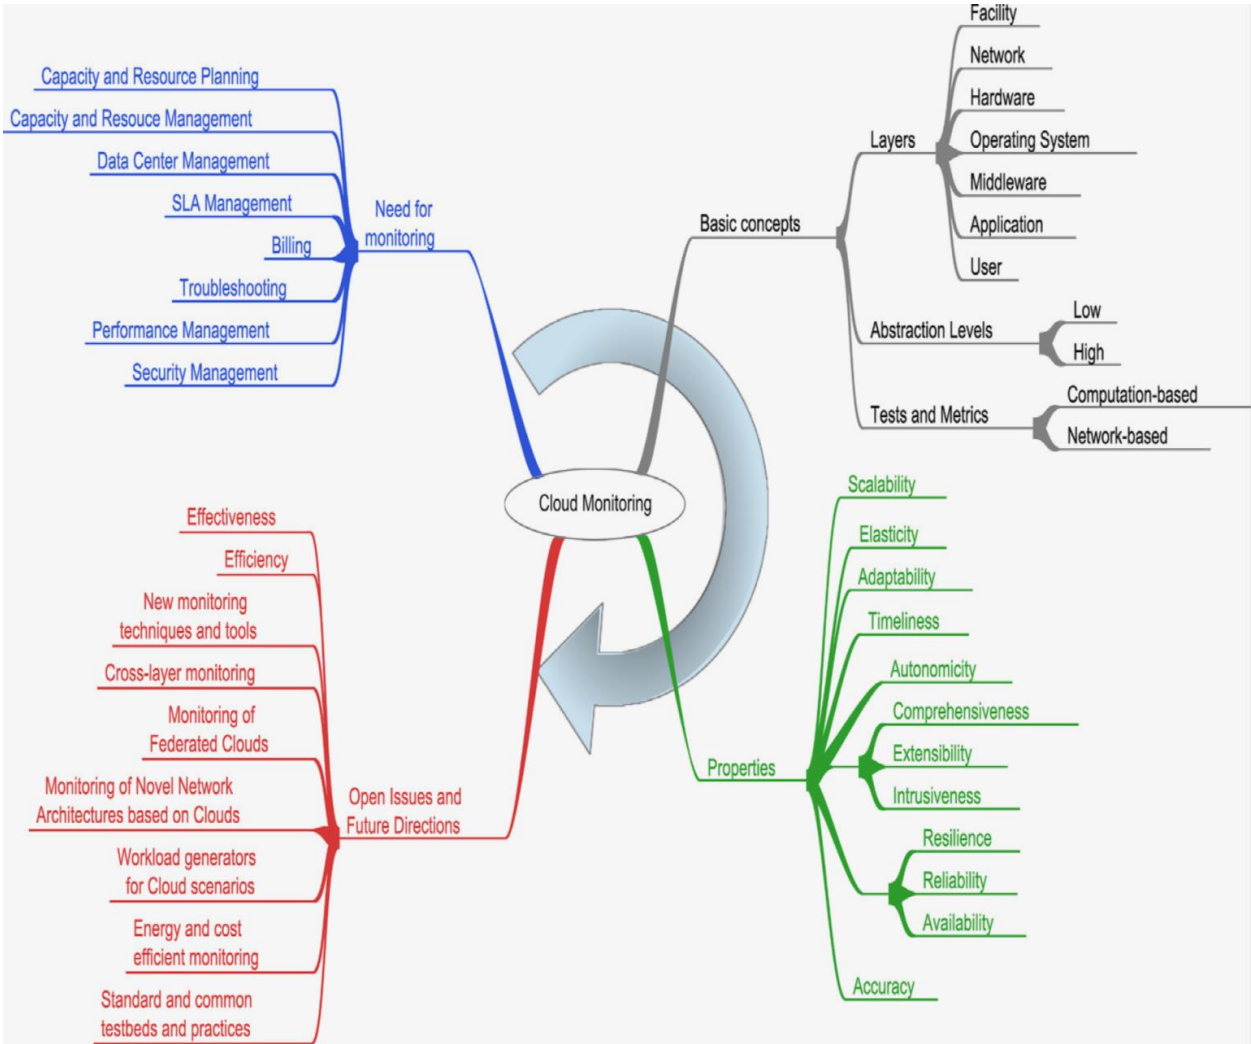

Figure 13: **Cloud monitoring: open issues, motivations, basic concepts, future directions, and properties** (Giuseppe Aceto, 2013)

## **Paper 10: “Performance Evaluation Approach for Multi-Tier Cloud Applications” (Arshdeep Bahga, 2013)**

This paper describes that Complex multi-level provisions conveyed in distributed computing situations can encounter quick changes in their assigned work. To guarantee exposition availability of such provisions, sufficient assets want to be provided so that the applications can confirm the requests of described assigned work levels, and in the meantime guarantee that administration level understandings are met.

Multi-level cloud requisitions can have a hypothetical arrangement designs with database servers, web application servers, and load balancers. Hypothetical conditions may present between servers at different levels. To help apparatus and limit arranging choices, execution testing methodologies with engineered workloads are utilized.

Exactness of an execution testing methodology is controlled by emulated sensible workloads and by nearly created manufactured workloads. Since multi-level requisitions can have differed sending designs and trademark assigned works, there is a demand for a non specific execution testing strategy that permits exactly demonstrating the execution of provisions.

This paper proposes a technique for execution testing of hypothetical multi-level requisitions. The assigned works of multi-level cloud requisitions are caught in two separate models- standards provision and task at hand ideals. An architectural miniature catches the organization arrangements of multi-level provisions. They suggest a quick sending prototype system that can assist in picking the greatest good and most financially savvy arrangements for multi-level provisions that accommodated the particularized execution necessities. They additionally depict a framework bottleneck discovery, methodology dependent upon a trial assessment of multi-level applications.

Achievement testing of cloud requisitions can uncover drawbacks in the framework what's more help provisioning and a limit arranging choices. With execution testing it is possible to anticipate an application execution under overwhelming workloads and distinguish bottlenecks in the framework so disappointments could be prevented.

# Impact of Cloud Computing

## On Business:

### 1. Speed: (Dominy, 2012)

- Normally attains speedier time to the arrangement.
- May show ROI speedier.
- Avoids postponements connected with long IT undertaking queues.
- Quicker time to market for easy to moderate prerequisites.
- The faster arrival of new characteristic.

### 2. Finance: (Beston, 2014)

- Distinguishing cloud administrations and examining bookkeeping models will help your association figure out how to continue most effectively and viable with exercises, for example, innovative work and income recognition.

### 3. Tax: (Beston, 2014)

- If you're purchasing or offering distributed computing administrations, it is discriminating to figure out what you're purchasing or offering. You may be renting supplies, preparing administration installments, or giving a permit for utilizing programming — these qualifications are essential and can have an effect on your organization's tax filings. The present tax law does not so much mirror the substances of distributed computing.

### 4. Risk and Compliance: (Beston, 2014)

- Cloud computing serve a risk, as it executes data and information into the hands of an outsider provider for the depot, processing, or holding. Buyers of cloud services will need to set the norm for the assessment of cloud computing providers; whereas workers will ask for to examine which cloud services to provide.

### **On the Education-E Learning:** (Hosam F. El-Sofany, 2013)

E-learning environment comes up after the impact of technology on a learning environment. As another sort of taking learning environment, it is initiating individuals' mainstream consideration. There is a different method for communicating it, for example, E-learning environment, net-learning environment, Virtual learning, and a computer learning environment etcetera. There are many advantages of cloud computing on E-learning and few of them are given below:

- It gives an answer to the issue of licensed software or authorized programming that requires consistent overhauling.
- The learning methodology obliges seeking and experimentation. An adaptability, gave by cloud innovations, empowers to change, and test also look at changed sorts of programming. Different types of software that might be inconceivable if buy each time new programming and equipment.
- Increase access to huge information stored in cloud.

### **Social Impact:** (Mullich, 2011)

- Everyone will become gamer as all the games will be easily provided with the help of cloud.
- We will get prior notice of any fixing needs to be done.
- As the cloud will expand, the computer will become unseen.
- With the help of cloud, stock records will be more transparent and trustworthy.
- If everything finds online, then anyone can give their suggestions related to the product.
- The product selling scenario will change with the help of cloud. People will buy the product from online communities as compared from a direct salesperson.
- With the help of cloud anyone can make a good decision as all information is available online.
- Cloud grants doctors to look after the patients wirelessly, gather information and treat according to the need.
- Cloud huge computational power will fade the language boundaries.
- Developing countries will develop into new markets and challengers.
- Laptop security will not break as it will not contain any private data anymore.

## Discussions:

### Advantages of Cloud: (Tsagklis, 2013)

- **Cost Effectiveness:** This is the greatest point of interest of distributed computing, accomplished by the disposal of the expenditure in individual programming or servers. By implementing cloud's abilities, organizations can spend on permit price and in that time dispense with overhead expenses, for example, the expense of information storage, programming upgrades, administration and so forth.
- **Continuous availability:** Advantage of cloud is that the end user can access the information from different geographical location and from a different time zone as all the information is stored in cloud.
- **Backup and Recovery:** Cloud provides good backup and recovery of the data as everything is in the cloud not on any physical device.
- **Environment friendly:** Cloud is an environment friendly as it uses less resource for computation. It means that when the servers are not in use, it frees the resources and consumes less power.
- **Flexibility and Redundancy:** Cloud architecture provides the flexibility and redundancy to its clients like automatic failover between hardware and disaster recovery.
- **Scalability and Performance:** Clouds can be changed according to the needs of user and computation speed is very good.
- **Quick deployment and ease of integration:** Cloud is very easy to deploy and software installation is automatically done in a cloud.
- **Increased Storage capacity:** Cloud can store a huge amount of data as compared to PC.
- **Location Independence:** Cloud is location independent and everyone can access the information from anywhere.
- **Small learning Curve:** Users find a cloud easy to learn and adopt like Google docs and Gmail.

## Disadvantages of cloud (Tsagklis, 2013)

- **Security and privacy:** Security is the major issue when we talked about the cloud computing. Organizations usually store their private and confidential data in cloud. After that its cloud service provider duty to control, safe and maintain the sensitive information. In the same way Privacy is another big concern because companies or users have to trust the providers that they will protect the sensitive information from the attackers.
- **Dependency and vendor lock in:** Another issue in a cloud is that the user has to depend on one service provider for the services. If the user wants to move to another provider, then it will be huge mess to transfer data from one cloud to another.
- **Technical difficulties and downtime:** Problems and downtime is also possible in cloud and systems might face de function and it will affect all the users. One should keep in mind that the whole system is based on the internet, and any problem in the system will ruin all the setup.
- **Limited control:** In cloud computing, all the services run on a virtual environment, and for that reason users and the companies have less control over the services.
- **Increased Vulnerability:** As important and crucial data stored on the cloud, now it achieves the attention of the attackers. We know nothing is completely secured on the internet and there are many examples from the past of security breaches.

## Future of the cloud: (Jansen, 2014)

- **Cloud Computing equals basic computing:** Just five years back, the cloud was just mumbled about with uncertainty or verbal confrontation. Today, innovation specialists' feels that distributed computing will turn into the standard for getting to back-end requisitions and gathering data inside one year from now.
- **Hybrid Cloud:** Expert house Gartner discharged a report uncovering that 50% of significant ventures will deploy hybrid cloud by 2017. As stated by tech titan SAP in affiliation with Wakefield Research, seventy-five percent, of hybrid cloud clients note less difficult IT forms by moving to hybrid format.

- **Shifting power of CIOs and IT Expert:** With the increase of cloud use, the role of IT Specialist and Chief Information Officers has changed. IT specialists will move far from creating new innovations, rather acting more like inner experts that evaluate and oversee how mechanical administrations give profits to diverse commercial ventures. In 2014, anticipate that organizations will give highlight vital and operational encounter over absolutely IT information for CIO positions.
- **Better Security:** Security is always an issue for cloud computing, but the latest research shows that most of the companies move to automated security with their own encryption keys. Forrester Research predicts that in the New Year, extensive merchants like HP, IBM, VMware and Cisco will buy new businesses committed to encoding organizations' information before it goes to the cloud. Toward the conclusion of 2014, anticipate that decoded information will practically vanish.
- **Progress in a cloud from small to medium sized businesses:** Forrester Research predicts that little and moderate sized organizations using on cloud results are required to develop 20% in the following five years. These organizations refer to the security benefits that cloud results have given, and also the capability to store new exercises like better client service on account of the time and expense funds by utilizing the cloud, as stated by a latest Microsoft study.
- **More Efficient Shopping in Retail Cloud Area:** As stated in a study by Accenture, retail cloud business sector is anticipated to multiply from \$4.2 billion in 2011 to \$15.1 billion in 2015. With such development, CIOs can improve business capacities for retail customers.
- **Australia as Major Cloud Competitor:** Taking into account Forrester Research, Australia comes in number two as a heading nation in public cloud results, straightforwardly following the United States. Despite the fact that Europe all in all exceeds Australia's IT development, the nation is rapidly creating its open cloud advertise much in the same way its reception of virtualization and cell phones emulated on the heels of the US. As stated by Forrester, China still falls behind Australia, staying in the early phases of virtualization and consolidation.

## Comparison of Cloud with Grid Computing

Figure 14: **Cloud vs. Grid Computing** (The Windows Club, 2014)

Cloud Computing	Grid Computing
1. Cloud is provided by the service providers.	Grid Computing is normally within the building or premises and it is possessed by a company.
2. Cloud is based on the concept of pay according to the use.	Grid is not based on this concept.
3. Cloud provides more services than Grid like data base support, web hosting, and multiple operating system.	Grid is made of roughly connected computers with each other with the help of network and it seems as a single device.

Table 2: **Comparison between cloud and grid computing.** (Chris Czarnecki, 2013)

	Cluster	Grid	Cloud
On-demand self-service	No	No	Yes
Broad network access	Yes	Yes	Yes
Resource pooling	Yes	Yes	Yes
Rapid elasticity	No	No	Yes
Measured service	No	Yes	Yes

Figure 15: **Difference between Cluster, Grid, and Cloud Computing** (Niels Fallenbeck)

## Conclusion:

In a nut shell we can say that cloud computing is emerging technology nowadays. It has lots of pros and cons, but the main issue in cloud computing is security and privacy of data. Many organizations are not interested to move their data on cloud as they believe they can take care of their sensitive data better than the cloud service provider.

As we have talked about the security issue there is another major issue; is that the user has to remain with one service provider for a long time or for whole life. If he wants to move to another service provider, it's just impossible as it will create mess to shift such huge amount of data.

Apart from many issues, still cloud computing is achieving new heights. Cloud computing can expand and shrink according to the needs of the user. Users have to pay only about the services which he has used just like electricity and water bills. Users do not have to bother how the cloud service provider will protect their data, but it's the service provider duty to do that.

Cloud computing is mainly good for small and medium sized business. As they can focus more on their business rather than spending money on the expensive IT Services. Cloud Computing is a very low cost way for organizations to get all the resources from one place and they have to only pay for that.

It is very cost effective and cheap way for organizations because they can have all resources from one place. Cloud computing is a better way to spread and share the resources; moreover one can access the resources easily and at low cost.

Apart from advantages and disadvantages the future of cloud is very bright, and researchers are constantly doing a lot of research to overcome the flaws.
